Empirical Methods for Computer Science (CS 5970)
Homework 2

October 28, 2008

This homework assignment is due on Tuesday, October 21st at 5:00pm. Your work may be handed in electronically (use the **Homework 2** digital dropbox on D2L) or in hardcopy form.

This assignment must be done individually: do not share/discuss your answers with others or look at the answers of others.

All data sets are contained within the hw2.mat file available on the main homework page.

Question 1

1. (10pts) Suppose that we are performing a robot navigation experiment in a busy building. The foot traffic level is a potential factor that could influence our performance metric. Should we consider this factor as an *extraneous* or *noise* variable? Explain in detail.

2. (10pts) What is the relationship between a hypothesis and *extraneous variables*?

3. (10pts) Explain the process of controlling a *noise variable*.

4. (10pts) Suppose that in comparing the performance of algorithms A and B, we find that we have a ceiling effect. What could you change about the experimental design to solve this problem?

5. (10pts) Define *censoring*. Why might we choose to use this technique? Can we always design an experiment to avoid the need for censoring data?

6. (10pts) Define *sampling bias*.

7. (10pts) True/False and explain: In a factorial experiment we must collect samples for all possible combinations of extraneous variables.

Question 2

1. (10pts) Define a *sampling distribution*.

2. (10pts) Under what conditions is it appropriate to use the Z-test?

3. (10pts) What are the key differences between the Z-test and the t-test?

4. (10pts) Which is more sensitive to differences between distributions: a paired t-test or a two-sample t-test? Under what conditions can you use the more sensitive one?

5. (10pts) In many situations, with enough samples, we can show a statistically significant difference between two distributions. Explain in detail why we may not want to use this capability.

Question 3

The matlab variable "dat3" contains a set of 3-tuple discrete observations (the data are represented as a single matrix). Columns 1 and 2 are independent variables; column 3 is a dependent variable.

(10pts) Describe the relationship between variables 1 and 3 in detail.

(10pts) Describe the relationship between variables 2 and 3 in detail.

(10pts) Is there an interaction effect of variables 1 and 2 on their influence of variable 3? One way to ask this question is whether variable 1 changes the effect that variable 2 has on variable 3.
